(54) Improved method and apparatus for optical interactance and transmittance measurements.

(57) Apparatus and a method are disclosed for the simultaneous or rapid sequential use of two or more different separations between the source and detector of the measuring apparatus to obtain spectral measurement data in diffuse transmission or "interaction" modes of collecting optical information from a specimen. The method and apparatus subsequently combine separate data taken from two or more different pathlengths to provide discrimination against undesired information while preserving or enhancing desired information. Additional reference information to normalize the optical signal is also provided. The optical and mechanical design of the optical probe also provides for transmittance, reflectance and interactance measurements on small amounts of specimen.

FIG. 1A

EP 0 574 601 A1

**Field of the Present Invention**

The present invention relates to an improved method and apparatus for performing optical interactance and transmittance measurements and, in particular, such method and apparatus where undesired information is discriminated against and desired information is enhanced. Reflectance measurements on small amounts of specimen are also encompassed by the invention.

**Background of the Problem****Solved by the Present Invention**

When optical energy is transmitted through a diffuse medium, scattering causes redirection of the rays so that the geometric pathlength between the energy entrance point and the energy exit point no longer defines the distance energy travels within the specimen. In addition, substantial energy may be scattered back towards the entrance or otherwise away from the exit region where detection occurs, thereby reducing the detected signal. This signal is therefore variable depending on the scattering characteristics of the particular region of the specimen traversed by the optical radiation.

A further cause of interference is nonhomogeneous or layered distribution of specimen characteristics, e.g., the layers of skin and fat which cover muscle tissue, the skin which covers the flesh of a fruit or vegetable, or the coating of windows through which measurements are to be made. Often, it is desirable to eliminate the affects of the surface layers to provide information on the underlying portions of the specimen. The present invention is directed to solving these problems which cause inaccuracies in spectroscopic determination of qualitative or quantitative characteristics of the specimen.

An additional problem is the making of diffuse reflectance and transmittance measurements on small specimens. Present reflectance instruments are generally designed to illuminate the specimen and detect reflected energy over several square centimeters of area. It is sometimes necessary to work with small amounts of specimen, for example a single seed, which must be recovered intact for future use. The present invention also addresses both diffuse transmission and diffuse reflection measurements of small specimens.

**Background Prior Art**

There has been a proposal for use of a transmission cell which had two different pathlengths through the specimen as a means of extending the dynamic range of spectral measurements in clear solutions. This proposal did not encompass separate measurement of the signals for the two pathlengths but rather the combined optical energy was detected. This results in a very nonlinear signal relative to concentration of an analyte within the specimen, however, the nonlinearity is predictable based on the known optical geometry of the cell.

Dual pathlength transmission cells with separate detection have been proposed to remove the effects of window coating in transmission measurements through clear liquids. This approach is equivalent to placing a second cell of different thickness in the reference beam of a dual-beam spectrometer. Effects common to the two paths, such as absorption due to the window material, equal deposits on the windows, atmospheric absorption, and the specimen absorption in the equal portion of the pathlength are canceled by taking the simple ratio of the signals derived from the two paths.

Norris ["A New Approach for the Estimation of Body Composition: Infrared Interactance", Joan M. Conway, Karl H. Norris and C.E. Bodwell, American Journal of Clinical Nutrition, Vol. 40, pp. 1123-1130 (1984)] first proposed measurement by means of "interaction", whereby a diffuse specimen is illuminated at one location and energy is collected some distance away on the same surface of the specimen. This is similar to diffuse reflection in that the primary mechanism returning energy to the detector is scattering, i.e., in the absence of scattering within the specimen, the incident energy would not impinge on the detection region. It differs from diffuse reflection, however, because the detection region does not include the illumination region, but is separated from it by some distance. Therefore, surface reflection of energy does not contribute to the detected signal and all the detected energy has traversed a minimum distance within the specimen, the separation distance between the source and detector. In this sense, "interaction" is similar to diffuse transmission. In general, the effective depth of penetration and the effective pathlength both increase as the spacing between the source and detection locations is increased.

Norris and others applying his method have used a single measurement of the energy passing through the specimen from the source region to the detection region. Typically, uniform geometric spacing between

the source area and the detection area is provided by using a central aperture surrounded a small distance away by a ring aperture. Either aperture could serve for the source while the other is used for detection. Both apertures are usually in contact with the specimen to prevent energy from leaking between the source and detection regions without traversing the specimen although thin windows between the apertures and the

5 Source have been used. An alternative structure has been to use equally parallel slit apertures, alternating between source and detection functions. In this case, all the source slit apertures were illuminated through one fiber optic bundle while energy was collected from all the detection apertures by means of a second bundle. Therefore, although more than two apertures exist, there is only one detected signal.

Diffuse transmittance and reflectance measurements are usually made on large volumes of specimen to

10 reduce errors by averaging the inhomogeneities. When only small specimens are available, the usual procedure is to grind each specimen into a fine powder and mix it with a nonabsorbing diluent or to spread it on a diffusely reflecting background so as to present a large area for reflectance measurement. There has been a proposed use of a reflecting cone into which the specimen is placed. The incident energy which does not impinge the specimen is returned in the direction of the source, and is rejected by the diffuse

15 reflectance detection geometry. Norris ["Determination of Moisture in Corn Kernels by Near-Infrared Transmittance Measurement", E.E. Finney, Jr. and Karl H. Norris, Transactions American Society of Agricultural Engineers, Vol. 21, pp. 581-584 (1978)] has made diffuse transmission measurements on single seeds by focusing the energy on the seed and placing a large area detector behind the opposite side. Careful attention must be paid to block the direct path past the seed. These methods for handling intact

20 small samples have been inconvenient at best.

### Summary of the Invention

In accordance with the invention, a method for improving optical interactance measurements comprises

25 the steps of providing illumination by way of a plurality of paths through a specimen having a characteristic to be measured, sensing two or more independent signals developed at the same time or in rapid sequence representing optical information from said specimen and processing said signals in accordance with appropriate modeling techniques to minimize inaccuracies in spectroscopic determination of qualitative or quantitative characteristics of the specimen.

30 Also in accordance with the invention, apparatus for improving optical interactance measurements comprises means for providing illumination through a specimen having a characteristic to be measured along a plurality of different paths, means for sensing optical information provided from an illuminated specimen, means for developing a plurality of independent signals corresponding in number to said plurality of paths, the signals representing the optical information obtained from the specimen and means for

35 processing the signals in accordance with appropriate modeling techniques to minimize inaccuracies in spectroscopic determination of quantitative or qualitative characteristics of the specimen. For a better understanding of the present invention, reference is made to the following description and accompanying drawings while the scope of the invention will be pointed out in the appended claims.

### Brief Description of the Drawings

In the drawings,

Figures 1A and 1B are a cross-sectional, length-wise view in partially schematic form of a two-ring, central aperture probe in accordance with the invention; and

45 Figure 2 is a diametric cross-section of a probe exhibiting a multiple ring aperture structure in accordance with the invention.

### Description of the Invention and Preferred Embodiments

50 A first aspect of this invention comprises the use of three or more optical apertures shared among the source and illumination functions so as to provide two or more independent signals for further processing and analysis. For example, in Figure 1A, a probe utilizing fiber optics is shown which has two ring apertures surrounding a central round aperture.

In Figure 1A, the probe 10 includes a cylindrical outer body 30 in which a concentric inner body 31 is

55 arranged. The inner body 31 tapers at the examining end to a central aperture 15. The outer body 30 constricts at the examining end to define a conical, inwardly directed wall. The tapered end of the inner body 31 defines a second conical wall. Between these two walls is disposed a conical dividing element 33. The angles defined by the two walls and the conical dividing element are preferably the same. Conical

annular spaces or rings (shown in cross-section as 14, 13, 12 and 11) are defined by the two walls and dividing element. In these annular spaces or rings are disposed, in conical fashion, optical fibers 16 and 17 for supplying illumination to the specimen. Within the inner body 31 are disposed one or more lenses 20 for focusing and transmitting incident light entering the aperture 15. A central fiber element 21, supported by element 32, receives light from the lenses 20, and directs it to the exit portion 21' of the probe. Illumination for fibers 16 and 17 is provided at 16' and 17'.

In this apparatus, each ring is used for illumination by fiber optic elements while the central detection aperture is connected by fiber optics to a detection system, such as a diode-array spectrophotometer. The central aperture in one embodiment is 1.2 mm diameter, and the inner ring has a mean diameter of 6 mm with a width of 1 mm. The mean spacing from the inner ring to the central aperture is therefore 3 mm and the minimum spacing is 1.9 mm. The outer ring has a mean diameter of 12 mm and a width of 1 mm, providing a mean spacing from source to detection of 6 mm and a minimum spacing of 4.9 mm.

In a preferred arrangement, the tip portion of the probe and the fiber optic elements at the tip portion are angled at approximately 26° with respect to the longitudinal axis of the probe.

It will be noted in Figure 1 that the central detection assembly is movable axially. For interactance measurements, the detection aperture at the distal end of this assembly is normally positioned in the same plane as the source ring apertures, however, it may be moved back and lenses inserted so as to image a detection area on the specimen into the aperture of the detection fibers. The lenses 20 in the inner body of the probe are interchangeable and the positions of the lenses and the central detection assembly are adjustable by means of spacers. In one embodiment, lenses and arrangements for three different specimen sizes for reflectance and one arrangement for interactance are listed in the following Table 1:

TABLE 1

	REFLECTANCE	REFLECTANCE	REFLECTANCE	INTERACTANCE
Specimen size	1.2 mm	0.7 mm	2.0 mm	
Stack position				
1	21 mm f length Plano-Convex Melles Griot 01LPX023	21 mm f length Plano-Convex Melles Griot 01LPX023	15.9 mm spacer	Fiber Optic Holder for central fiber
2	6 mm spacer	6 mm spacer	Melles Griot 01LPX065	Spacer
3	21 mm Melles Griot 01LPX023	36 mm Melles Griot 01LPX065	6 mm spacer	Spacer
4	17.7 mm spacer	17.7 mm spacer	21 mm Melles Griot 01LPX023	Spacer
5	15 mm spacer	15.9 mm spacer	17.7 mm spacer	Spacer
6	Fiber Optic Holder for Central Fiber	15 mm spacer	15 mm spacer	Spacer
7	15.9 mm spacer	Fiber Optic Holder for Central Fiber	Fiber Optic Holder for Central Fiber	Spacer

This reimaging allows control of the size of the detection area and the angular cone within which energy is detected by changing the lenses and their spacing.

It may also be seen in Figure 1 that the energy source fibers are arranged in conical form. The energy exits at a mean angle of approximately 45° based on the angle of the fibers and the refraction at their polished ends. For intertance measurements on specimens which have limited backscatter, introduction of the energy at an angle directed toward the detector improves the efficiency. This feature also provides for diffuse reflectance and transmittance measurements using the same probe as discussed below.

In order to obtain separate signals for each spacing, the two source rings may be alternately illuminated or the source energy may be modulated differently, e.g., at two different frequencies or with different time sequence codes. The detection signal is then gated or demodulated to separate the information from the two different sources. As shown in Figure 1B, each source fiber optic bundle, preferably, has a small percentage of its input fibers brought out so that the associated source intensity and modulation can be monitored. It will be obvious to one skilled in the art that additional source rings may be provided, each with its distinctive modulation, and that the operation may be reversed to provide a single source by using two or more detection rings coupled to multiple or time-shared detection means. For example, Figure 2 shows a design comprising 10 large area (8 to 28 mm<sup>2</sup> active area) ring apertures, nominally designated as source rings, and a central aperture plus 2 additional rings of smaller area (2.9 to 3.4 mm<sup>2</sup>) nominally considered as detection rings. The source ring active area is adjusted by the density of active fibers within each ring. This structure allows selection of a wide variety of spacings and locations for the measurements using combinations of the three different detection apertures and 10 source apertures. While the examples shown here show ring geometries, other geometries, such as parallel slits or small apertures, which provide substantially constant values of the spacing between all points within a given source aperture and those within a given detection aperture may be used.

Having derived separate signals for the two or more paths, they are processed and combined in accordance with a linear or nonlinear model of the system response to variations in the concentration of the analytes and interferences present in the spectrum. In the simplest cases, for example, the cancellation of the optical effects of deposits on the window through which the measurements are being made, it may suffice to use the ratio of the signal from one spacing to that of a second spacing. This assumes that the deposits have the same transmission spectrum  $T_1$  for both paths, as would be true for a uniform coating, and that the specimen behind the window is relatively homogeneous with an intertance spectrum,  $I$ . The signals may then be expressed as  $K_1 \cdot T_1 \cdot I_1$  and  $K_2 \cdot T_1 \cdot I_2$  where  $K_1$  and  $K_2$  are system functions involving the relative source intensities, the gain through the system, scattering losses and similar factors. The ratio is therefore  $(K_1/K_2) \cdot (I_1/I_2)$  and the window coating transmission has been eliminated from the result. Note that any factors common to  $K_1$  and  $K_2$  are also canceled as in the normal use of a reference and the remainder factors may be adjusted so that the  $K$  factor becomes unity. Taking the log of the ratio yields "absorbance"  $A$  equal to  $\log(I_1) - \log(I_2)$ . If  $I$  is exponentially related to the product spacing  $t$  and the analyte absorptivity  $a$ ,  $\log(I)$  will equal  $(a \cdot t)$  and the log difference becomes  $a \cdot (t_1 - t_2)$  where  $a$  is the "absorptivity" spectrum which is linearly related to concentration. In many, if not most, practical cases,  $\log(I)$  is not linearly related to the product of spacing with absorptivity and absorptivity is not linearly related to concentration. Therefore, this invention contemplates use of other linear and nonlinear chemometric models to define the relationships and provide quantitative analyte information.

The situation is further complicated if the specimen is nonhomogeneous, such as the cases with layers described above. Here, the various signals are derived by absorption of light through different combinations of materials within the specimen. All the signals contain information on the surface layers while the signals derived from the larger spacings contain information on the deeper layers that is diminished or lacking in the signals measured with smaller spacings. When it is desired to differentiate between the information derived from deep within the sample and that obtained from layers closer to the surface, these signals may be combined in a linear or nonlinear chemometric model so as to extract the desired information. In this case, it is helpful to have the input energy for each source aperture as an additional measured quantity for use in the modeling. Each class of specimens requires a different form of model, and subclasses require determination of various model parameters during the calibration process.

Another aspect of the invention is the use of the probe for diffuse reflection measurements of small specimens. The specimen may be held in a small hole drilled in a flat plate mounted approximately 2 to 4 mm from the end of the fiber-optic probe. It is illuminated via one or both of the outer ring bundles at an angle of incidence of approximately 45 degrees. The plate is finished with a mirror surface so that incident energy outside the area of the specimen is reflected at approximately 45 degrees from the normal. The diffusely reflected energy is collected by imaging the specimen surface on the central fiber bundle via lenses whose optical axes are coincident with the axis of the probe assembly. The power and spacing of the lenses may be selected so as to select the desired sample area. Because the collection is normal to the specimen and specimen holder and energy is reflected by the holder and by any window above the

specimen at an angle, this specularly reflected energy is rejected from the measurement. If desired, a diffuse or specular reflector may be placed behind the specimen to increase its apparent depth by a factor of at least two.

Alternatively, the axis of the probe may be positioned vertically with the apertures at the top and a transparent window, such as a microscope slide, positioned with its upper surface at the appropriate distance from the apertures. Specimens may be placed on the window for measurement. Three measurements may be made:

- a) no specimen (just a slide);
- b) specimen
- 10 c) reference spectrum using a diffuse reflecting material such as SPECTRALON™ (a trademark of Labsphere, Inc.).

The "no specimen" energy spectrum is subtracted from the spectrum of the specimen and the spectrum of the reference to correct for residual energy reflected or scattered from the window.

Still another aspect of the invention is the measurement of diffuse transmission through small specimens. The specimen is mounted in a hole on a plate and illuminated as previously described for reflectance measurements. The receiving fiber-optic bundle is placed behind the sample so as to collect the transmitted energy. The conical illumination pattern is helpful in achieving rapid diffusion of energy within the specimen thereby improving the repeatability of measurements on small specimens. In addition, by using two collecting fiber-optic bundles, simultaneous or time shared measurement of both, the diffusely transmitted and diffusely reflected energy is possible. The combination of these two measurements allows additional information to be obtained concerning the absorption and scattering characteristics of the specimen.

Still another embodiment utilizes the probe as described above for reflection and an additional fiber bundle is employed behind the specimen to illuminate it. Therefore, the same receiver is utilized for transmittance and reflectance with two different illumination sources being provided. A switching arrangement may be used to alternate between the illumination sources.

In each case, the central detection element may comprise the detector itself rather than the fiberoptic detector bundle.

While the above described probe is preferred, an alternate embodiment can be constructed where the direction of light flow can use the light source being provided at the control aperture and one or more of the fiber optic bundles responsive to specimen information.

While the foregoing description and drawings represent the preferred embodiments of the present invention, it will be obvious to those skilled in the art that various changes and modifications may be made therein without departing from the true spirit and scope of the present invention.

## Claims

1. A method for improving optical interactance measurements comprising the steps of:
  - providing illumination by way of a plurality of different paths through a specimen having a characteristic to be measured;
  - sensing a plurality of independent signals developed at the same time or in rapid sequence representing optical information obtained from said specimen in response to said illumination, each independent signal corresponding to a particular path; and
  - processing said signals in accordance with appropriate modeling techniques to minimize inaccuracies in spectroscopic determination of qualitative or quantitative characteristics of the specimen.
2. The method of claim 1 including the step of providing the illumination of the specimen simultaneously along said different paths.
3. The method of claim 1 including the step of providing the illumination of the specimen sequentially along said different paths.
4. The method of claim 2 including the step of providing the illumination of the specimen modulated at different frequencies along said different paths respectively for distinguishing one independent sensed signal from another.
5. The method of claim 2 including the step of providing illumination of the specimen with different time sequence codes along said different paths respectively for distinguishing one independent sensed

signal from another.

6. The method of claim 1 including the step of providing the illumination at an angle with respect to the optic axis of the detection means.
- 5 7. Apparatus for improving optical interactance measurements comprising:  
means for providing illumination to a specimen having a characteristic to be measured along a plurality of different paths;  
means for sensing optical information developed by said illumination provided from an illuminated  
10 specimen;  
means, responsive to said sensed optical information, for developing a plurality of independent signals corresponding in number to said plurality of paths, said signals representing said optical information obtained from said specimen; and  
means for processing said signals in accordance with appropriate modeling techniques to minimize  
15 inaccuracies in spectroscopic determination of quantitative or qualitative characteristics of the specimen.
8. The apparatus of claim 7 including means for providing the illumination simultaneously along said paths.
- 20 9. The apparatus of claim 7 including means for providing the illumination sequentially along said paths.
10. The apparatus of claim 7 including means for modulating said illumination provided to said paths so that each path had a different modulating characteristic, said apparatus also including means responsive to said independent signals for demodulating said signals.
- 25 11. Apparatus for improving optical interactance, transmittance and reflectance measurements comprising:  
an elongated probe having a body portion and a tip portion, the body portion comprising a central tubular element surrounded by an annular outer element;  
30 the tip portion having a central aperture which communicates with said central tubular element and at least one ring which communicate with said annular outer element;  
the ring or rings in said tip portion being angled with respect to the longitudinal axis of the probe;  
a number of fiber optic bundles whose number corresponds to said ring or rings being disposed within said outer element, each bundle being arranged at one end to exit at a respective ring and, at  
35 the other end, at least one such bundle to be connected to a source of illumination; and  
optical means disposed in the central tubular element for receiving optical information resulting from applied illumination to a specimen from said central aperture from a specimen and for conveying said information to a sensing device so as to develop signals representing said specimen optical information.
- 40 12. The apparatus of claim 11 wherein each fiber optic bundle is arranged at the other end to be connected to a source of illumination.
13. The apparatus of claim 11 also including means to process said signals in accordance with appropriate modeling techniques to minimize inaccuracies in spectroscopic determination of qualitative or quantitative characteristics of the specimen.
- 45 14. The apparatus of claim 11 wherein said tip portion and fiber optic elements at the tip portion are angled at approximately 26° with respect to the longitudinal axis of the probe.
- 50 15. The apparatus of claim 11 including at least one lens disposed in said central tubular element for focusing the optical information received in said central aperture and means responsive to the focused information for forming a signal representing said information.
- 55 16. The apparatus of claim 15 wherein said means responsive to the focused information includes a fiber optic element for conveying the focused optical information to a detector responsive to the optical information conveyed by the fiber optic element.

17. The apparatus of claim 11 also including fiber optic means and a detector for providing a signal representative of the illumination received by the specimen.
18. The apparatus of claim 15 including means for allowing the focusing of said lenses to be changed.
- 5 19. In a method of using apparatus for improving optical interactance measurements comprising means for providing illumination to a specimen having a characteristic to be measured along a plurality of different paths, means for sensing optical information developed by said illumination provided from an illuminated specimen, means, responsive to said sensed optical information, for developing a plurality of  
10 independent signals corresponding in number to said plurality of paths, said signals representing said optical information obtained from said specimen, and means for processing said signals in accordance with appropriate modeling techniques to minimize inaccuracies in spectroscopic determination of quantitative or qualitative characteristics of the specimen, said method including the step of arranging the tip of the probe adjacent a specimen of small size so that reflected energy from said specimen is  
15 directed to said central aperture.
20. In a method of using apparatus for improving optical interactance measurements comprising means for providing illumination to a specimen having a characteristic to be measured along a plurality of different paths, means for sensing optical information developed by said illumination provided from an illuminated specimen, means, responsive to said sensed optical information, for developing a plurality of  
20 independent signals corresponding in number to said plurality of paths, said signals representing said optical information obtained from said specimen, and means for processing said signals in accordance with appropriate modeling techniques to minimize inaccuracies in spectroscopic determination of quantitative or qualitative characteristics of the specimen, said method including the steps of arranging  
25 the tip of the probe adjacent a specimen of small size and using fiber optic elements to receive energy transmitted through said specimen to said central aperture.
21. In a method of using apparatus for improving optical interactance measurements comprising, means for providing illumination to a specimen having a characteristic to be measured along a plurality of different  
30 paths, means for sensing optical information developed by said illumination provided from an illuminated specimen, means, responsive to said sensed optical information, for developing a plurality of independent signals corresponding in number to said plurality of paths, said signals representing said optical information obtained from said specimen, and means for processing said signals in accordance with appropriate modeling techniques to minimize inaccuracies in spectroscopic determination of  
35 quantitative or qualitative characteristics of the specimen, said method including the step of providing a further source of illumination, arranging the tip of the probe adjacent a near side of a specimen of small size, arranging the further source of illumination on a far side of said specimen, using said probe so that reflected energy from said specimen is directed to said central aperture and/or energy transmitted by said further source through said specimen is directed to said central aperture.  
40
22. In a method as in claim 21 including the step of selectively choosing an operational mode of reflectance, transmittance or combined reflectance and transmittance.
23. In a method of using apparatus for improving optical interactance measurements comprising means for  
45 providing illumination to a specimen having a characteristic to be measured along a plurality of different paths, means for sensing optical information developed by said illumination provided from an illuminated specimen, means, responsive to said sensed optical information, for developing a plurality of independent signals corresponding in number to said plurality of paths, said signals representing said optical information obtained from said specimen, and means for processing said signals in accordance  
50 with appropriate modeling techniques to minimize inaccuracies in spectroscopic determination of quantitative or qualitative characteristics of the specimen, said method including the steps of providing a further detector for developing an electrical signal responsive to illumination, arranging the top of the probe adjacent the near side of a specimen of small size, arranging said further detector on a far side of said specimen, using said probe so that reflected energy from said specimen is directed to said  
55 central aperture and/or energy transmittal by said probe is detected by said further detector.
24. In a method as in claim 23 including the step of selectively choosing an operational mode of reflectance, transmittance or combined reflectance and transmittance.

25. Apparatus for improving optical interactance, transmittance and reflectance measurements comprising:  
an elongated probe having a body portion and a tip portion, the body portion comprising a central tubular element surrounded by an annular outer element;  
the tip portion having a central aperture which communicates with said central tubular element and  
5 a plurality of rings which communicate with said annular outer element;  
the rings in said tip portion being angled with respect to the longitudinal axis of the probe;  
a plurality of the fiber optic bundles whose number corresponds to said plurality of rings being disposed within said outer element, at least one bundle being arranged at one end to exit at a respective ring for receiving specimen information and, at the other end, adapted to be connected to a  
10 detector for developing a signal; and  
said central tubular element being connected at one end with a source of illumination, which illumination will exit at the central aperture;  
whereby independent signals responsive to said illumination representing said specimen information may be developed.  
15
26. In a method of using apparatus for improving optical interactance, transmittance and reflectance measurements comprising an elongated probe having a body portion and a tip portion, the body portion comprising a central tubular element surrounded by an annular outer element, the tip portion having a  
20 central aperture which communicates with said central tubular element and at least one ring which communicate with said annular outer element, the ring or rings in said tip portion being angled with respect to the longitudinal axis of the probe, a number of fiber optic bundles whose number corresponds to said ring or rings being disposed within said outer element, each bundle being arranged at one end to exit at a respective ring and, at the other end, at least one such bundle to be connected to a source of illumination, and optical means disposed in the central tubular element for receiving  
25 optical information resulting from applied illumination to a specimen from said central aperture from a specimen and for conveying said information to a sensing device so as to develop signals representing said specimen optical information, said method including the step of arranging the tip of the probe adjacent a specimen of small size so that reflected energy from said specimen is directed to said central aperture.  
30
27. In a method of using apparatus for improving optical interactance, transmittance and reflectance measurements comprising an elongated probe having a body portion and a tip portion, the body portion comprising a central tubular element surrounded by an annular outer element, the tip portion having a  
35 central aperture which communicates with said central tubular element and at least one ring which communicate with said annular outer element, the ring or rings in said tip portion being angled with respect to the longitudinal axis of the probe, a number of fiber optic bundles whose number corresponds to said ring or rings being disposed within said outer element, each bundle being arranged at one end to exit at a respective ring and, at the other end, at least one such bundle to be connected to a source of illumination, and optical means disposed in the central tubular element for receiving  
40 optical information resulting from applied illumination to a specimen from said central aperture from a specimen and for conveying said information to a sensing device so as to develop signals representing said specimen optical information, said method including the steps of arranging the tip of the probe adjacent a specimen of small size and using fiber optic elements to receive energy transmitted through said specimen to said central aperture.  
45
28. In a method of using apparatus for improving optical interactance, transmittance and reflectance measurements comprising an elongated probe having a body portion and a tip portion, the body portion comprising a central tubular element surrounded by an annular outer element, the tip portion having a  
50 central aperture which communicates with said central tubular element and at least one ring which communicate with said annular outer element, the ring or rings in said tip portion being angled with respect to the longitudinal axis of the probe, a number of fiber optic bundles whose number corresponds to said ring or rings being disposed within said outer element, each bundle being arranged at one end to exit at a respective ring and, at the other end, at least one such bundle to be connected to a source of illumination, and optical means disposed in the central tubular element for receiving  
55 optical information resulting from applied illumination to a specimen from said central aperture from a specimen and for conveying said information to a sensing device so as to develop signals representing said specimen optical information including the step of providing a further source of illumination, arranging the tip of the probe adjacent a near side of a specimen of small size, arranging the further

source of illumination on a far side of said specimen, using said probe so that reflected energy from said specimen is directed to said central aperture and/or energy transmitted by said further source through said specimen is directed to said central aperture.

5 29. In a method as in claim 28 including the step of selectively choosing an operational mode of reflectance, transmittance or combined reflectance and transmittance.

30. In a method of using apparatus of for improving optical interactance, transmittance and reflectance measurements comprising an elongated probe having a body portion and a tip portion, the body portion  
10 comprising a central tubular element surrounded by an annular outer element, the tip portion having a central aperture which communicates with said central tubular element and at least one ring which communicate with said annular outer element, the ring or rings in said tip portion being angled with respect to the longitudinal axis of the probe, a number of fiber optic bundles whose number corresponds to said ring or rings being disposed within said outer element, each bundle being arranged  
15 at one end to exit at a respective ring and, at the other end, at least one such bundle to be connected to a source of illumination, and optical means disposed in the central tubular element for receiving optical information resulting from applied illumination to a specimen from said central aperture from a specimen and for conveying said information to a sensing device so as to develop signals representing said specimen optical information, said method including the steps of providing a further detector for  
20 developing an electrical signal responsive to illumination, arranging the top of the probe adjacent the near side of a specimen of small size, arranging said further detector on a far side of said specimen, using said probe so that reflected energy from said specimen is directed to said central aperture and/or energy transmitted by said probe is detected by said further detector.

25 31. In a method as in claim 30 including the step of selectively choosing an operational mode of reflectance, transmittance or combined reflectance and transmittance.
